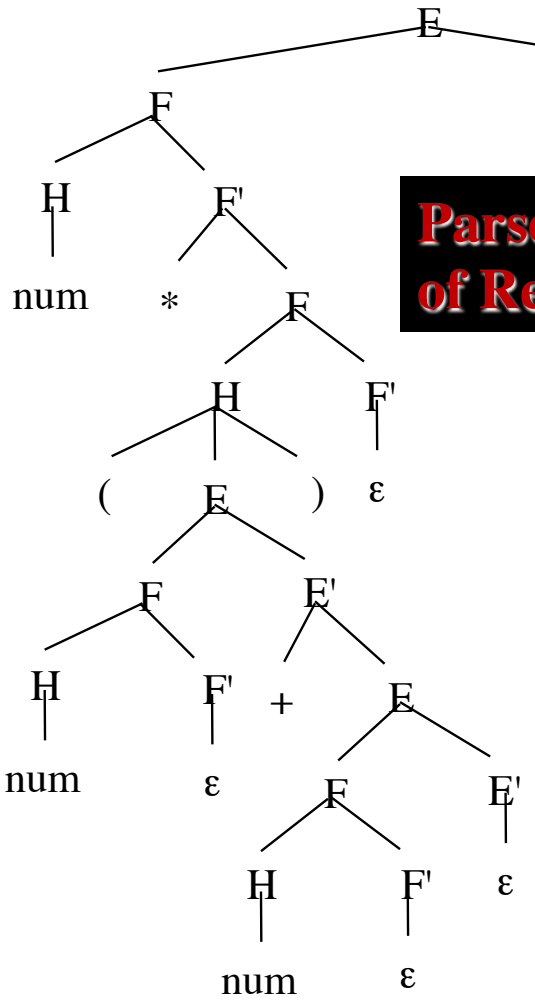
From Syntax Analyzers to Tree/Code Generators

- **Parse Trees**
- **Syntax Trees and Abstract trees**
- **How to extend Analyzers: Attribute Grammars**
- **Trees and Code as Grammar Attributes**

Parse Tree



Parse Tree relates the **Language Phrases** with **a way of Recognizing** them, using a **Specific Grammar**

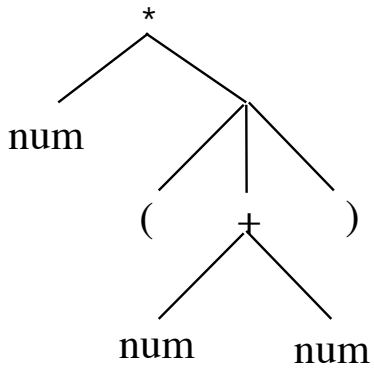
E::= E (+|*) E | num | (E)

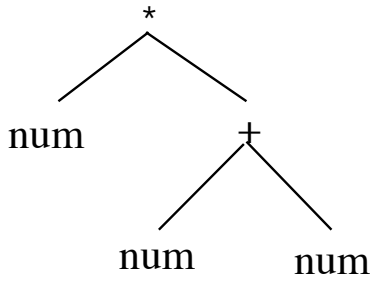
E::= F E'[0]
E'::= + E[1] | ε [2]
F::= H F'[3]
F'::= * F [4] | ε [5]
H::= num[6] | (E)[7]

E::= F + E | F
F::= H * F | H
H::= num | (E)

Syntax and Abstract Trees

Sometimes, Parse Tree may be **Useless** or too **Expensive**





It relates **Terms** with the **Subterms in their concrete syntax** form

It relates **Terms** with the **Subterms ignoring any concrete aspect**

We need a general framework for Recognizing Phrases and Producing different kinds of information about them

Attribute Grammars

One **Methodology**,

One **Technique**,

One **Tool** for

Property Analyses (possibly Contextual)
and

Code Generation

Attribute Grammars
Syntax - 1

Let $G = \{\Sigma, V, s, P\}$ be a Grammar
- $P \subseteq V \times E_{\Sigma+V}$
- $L(G) = I(G)$ -- see later on

Let $B \in \Sigma + V$ be a (grammatical symbol of G).
Let $\{\mathbf{a_i}\}$ be a family of symbols, called attribute symbols.
Attribute a_i of B be
- a syntactic entity denoted by $\mathbf{B.a_i}$
- with, as associated meaning, a value that depends on the Parse Trees in which the attribute is considered
- the value type, if any, depends on the Attribute Grammar, extending G

$\mathbf{Meta_{\{ai\}}}$ be a Programming Language extended with attributes, viewed as constant (final variables)
Actions $\{\alpha_i\} \subseteq \{a_i\} \times Meta_{\{ai\}}$ be assignments of the form $\mathbf{B.a_i} = e_i$ where $e_i \in \mathbf{Meta_{\{ai\}}}$

Let $G^A \equiv \{\Sigma, V, s, P^A, \{a_i\}\}$ be an atribute grammar extending G. Then:
- $G^A\downarrow \equiv \{\Sigma, V, s, P\} = G$, *con* $P = P^A\downarrow$
- $P^A \equiv P \times \{\alpha_i\}$
- …

Attribute Grammars
Syntax - 2

Let G = {∑,V,s,P} be a Grammar ….

…
Actions **{α}** be assignments of the form $\mathbf{B.a_i} = e_i$ where $e_i \in \mathbf{Meta_{\{ai\}}}$

Let $G^A \equiv \{\sum, V, s, P^A, \{a_i\}\}$ be an attribute grammar extending G. Then:

- $G^A\downarrow \equiv \{\sum, V, s, P\} = G$, *con* $P = P^A\downarrow$
- $P^A \equiv P \times \{\alpha\}$
- $\forall p \in P^A$, let $p \equiv B := \beta \{X1.a1 = e1, \ldots, Xk.ak = ek\}$
  - $\{X1, \ldots, Xn\} \subseteq Sym(\beta) + \{B\}$
  - $Sym(e1) + \ldots + Sym(ek) \subseteq Sym(\beta) + \{B\}$
  - no side effects (otherwise are called, SDD for Syntax Directed Definition

where: $Sym(U) \subseteq \sum + V$ is the Set of grammatical symbols in U

Attribute Grammars
Syntax - Example

Let $G^A \equiv \{\Sigma, V, s, P^A, \{a_i\}\}$ be an attribute grammar extending G. Then:

- $G^A\downarrow \equiv \{\Sigma, V, s, P\} = G$, *con* $P = P^A\downarrow$
- $P^A \equiv P \times \{\alpha\}$
- $\forall p \in P^A$, let $p \equiv B := \beta \{X1.a1=e1, \ldots, Xk.ak=ek\}$
  - $\{X1, \ldots, Xn\} \subseteq Sym(\beta)+\{B\}$
  - $Sym(e1)+\ldots+Sym(ek) \subseteq Sym(\beta)+\{B\}$
  - no side effects (otherwise are called, SDD for Syntax Directed Definition}

Where: $Sym(U) \subseteq \Sigma+V$ is the Set of grammatical symbols in U

$S ::= E \{E.d := \phi\}$

E::= F E' {E'.d=E.d+1}
E'_1::= + F E'_2 {E'_2.d=E'_1.d+1}
E'::= ε {ε.d=E'.d}

What about the type of attribute of d?
What about the value of E.d?

What does this grammar define ?

Attribute Grammars Semantics i.e. Meaning

E::= F E' {E'.d=E.d+1}
E'_1::= + F E'_2 {E'_2.d=E'_1.d+1}
E'::= ε {ε.d=E'.d}

What does this grammar define ?

An Attribute Grammar defines a set of *Parse Trees* whose *nodes* are extended with *attribute-value pairs* according to the Grammar and the Parse Tree

We need to define structures for:

- Labeled Trees
- Labeled Trees with Attributes

before giving semantics

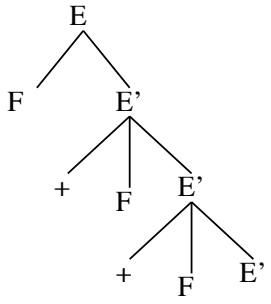
Binary Relations: Tree, Labeled Tree

Trees (are binary relations):

- $T = \langle R, E \subseteq R^2 \rangle$
- $T = \langle R, E \subseteq R^2, L:R \to U \rangle$ -- *labeled on a set U*

where: R=*set of the nodes* E=*set of the (directed) edges* L= *Labeling Function on U*

Operators: root*: T --> R*, arity: *R --> N*, son*: T* x *N --> T*
Selectors: R(T)= R, E(T)=E, L(T)=L
Shortening: sons: $T \to T^N$, L: $T^N \to U^N$
$sons(T)=son(T,1)\ldots son(T,arity(root(T)))$ $L(T_1,\ldots,T_k)=L(root(T_1))\ldots L(root(T_k))$



T = <R(T),E(T),L(T)>, where:
R(T) = {0,1,2,3,4,5,6,7,8}
L(T) = {(0,E),(1,F),(2,E'),(3,+),(4,F),(5,E'),(6,+),(7,F),(8,E')}
E(T) = {(0,1),(0,2),(2,3),(2,4),(2,5),(5,6),(5,7),(5,8)}

Grammars and Parse Trees

- I(G) is the set of Parse Trees of G

- I(G) is obtained by =>*, using => on the tree set T(G).

Let: $G \equiv <\Sigma, V, s \in V, P \equiv \{x_i ::= x_{i,1} \ldots x_{i,ki} \mid i \leq |P|\}>$

$T(G) \equiv \{T \equiv <R, E \subseteq R^2, L:R \to \Sigma \cup V> \mid$

$\text{if } (l,r) \in E \text{ then } (l,r) \in \{(l,r_1),\ldots,(l,r_h) \mid L(l)=x \;\&\; L(r_i)=x_i \;\&\; x ::= x_1 \ldots x_h \in P\} \subseteq E\}$

$\Rightarrow \equiv \{(T,U) \in T(G)^2 \mid \text{either } arity(root(T))=0 \;\&\; L(root(T))=x=L(root(U)) \;\&\; L(sons(U))=x_1 \ldots x_k$

$\text{for some } x ::= x_1 \ldots x_k \in P \;\&\; arity(son(U,i))=0 \text{ forall } 1 \leq i \leq k$

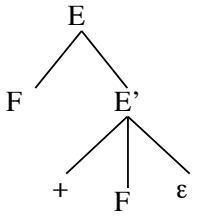
$\text{or } L(root(T))=L(root(U)) \;\&\; son(T,j)=son(U,j)\ (\forall j \in 1..k \backslash i) \;\&$

$son(T,i) => son(U,i) \text{ for } 1 \leq i \leq k \equiv arity(root(T))\ \}$

$$\boldsymbol{I(G) \equiv \{T \mid T_s \Rightarrow^* T \;\&\; arity(root(T_s))=0 \;\&\; L(root(T_s))=s \;\&\; L(leaves(T)) \in \Sigma^*\}}$$

$\text{where: } leaves(T)=T, \quad \text{if } arity(root(T))=0$

$leaves(son(T,1)) \ldots leaves(son(T,k)), \quad \text{if } arity(root(T))=k \neq 0$



E::= F E'
E'::= + F E'
E'::= ε

AST: Abstract Syntax Trees

Abstract Syntax Trees are the elements of:

One Binary, Anti-Symmetric, Relation ">" on Terms s.t:

$$f_k(t_1,\ldots,t_k) > t_i \qquad (\forall\, 1 \le i \le k \;\&\; f_k(t_1,\ldots,t_k), t_i \in Terms)$$

Equally: $> \equiv \{(f_k(t_1,\ldots,t_k),t_i) \mid 1 \le i \le k,\ f_k(t_1,\ldots,t_k),t_i \in T_\Sigma\}$

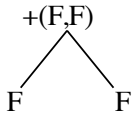
where: $T_\Sigma \equiv \{f_k(t_1,\ldots,t_k) \mid f_k \in \Sigma \;\&\; t_1,\ldots,t_k \in T_\Sigma\}$ *--- Terms on* Σ

Equally: $> \equiv \langle R, E \subseteq R^2, L:R \to T_\Sigma \rangle$

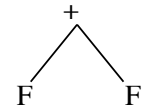
where: $E \equiv \{(l, r_1),\ldots,(l, r_k) \mid L(l)=Opt(f_k(t_1,\ldots,t_k)) \;\&\; L(r_i)=Opt(t_i)\ (\forall f_k(t_1,\ldots,t_k) \in T_\Sigma)\}$

$\Sigma = \{F_0, +_2\}$
$T_\Sigma ::= \{F\} \cup \{+(u,t) \mid u,t \in T_\Sigma\}$

Opt: $T_\Sigma \to \Sigma$
$Opt(f_k(t_1,\ldots,t_k)) = f_k$



or



For a different label -ing function L

Attribute Grammars Semantics

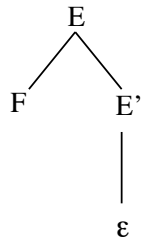
$T = \langle R, E \subseteq R^2, L: R \to U \rangle$ --- *U-labeled Trees*
$T^A = \langle T, L_{\{ai\}}: R(T) \to W_{\{ai\}} \rangle$ --- *U-labeled Trees attributated by values on* $W_{\{ai\}}$

Grammar: $G = \{\Sigma, V, s, P\}$
- $P \subseteq V \times E_{\Sigma+V}$
- $L(G) = I(G)$

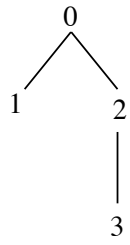
Attribute Grammar: $G^A \equiv \{\Sigma, V, s, P^A, \{a_i\}\}$
- $G^A\downarrow \equiv \{\Sigma, V, s, P\} = G$, *con* $P = P^A\downarrow$
- $P^A \equiv P \times \{\alpha\}$
- $L(G^A) \equiv \{\langle T, L_{\{ai\}} \rangle \mid T \in L(G^A\downarrow)$ & $\forall r_0 \in R(T)$:
  - $sons(r_0) = r_1, \ldots, r_n, (\forall i \in 0..n) L(r_i) = B_i$, $B_0 ::= B_1, \ldots, B_n \{B_i.a_{ji} = e_{i,ji}\}^{i \in 0..n} \in P^A$
  - $L_{aj}(r_i) \equiv Sem_{Meta}(e_{i,j}\,[L_{ak}(r_h)/B_h.a_k]^{(h \neq i)\ or\ (k \neq j)})\}$
    - *E[V/x]* means *E* where the value V is replacing *x*
    - $F^{c(i)}$ means $F[V_1/i] \ldots F[V_n/i]$ for $c(i) = \{V_1, \ldots, V_n\}$

Attribute Grammar Example

E::= F E' {E'.d=E.d+1}
E'_1::= + F E'_2 {E'_2.d=E'_1.d+1}
E'::= ε {ε.d=E'.d}



parse tree



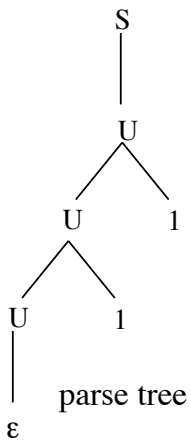
The effective T

$$T^A=\{<R=\{0,1,2,3\}, E, L=\{(0,E),(1,F),(2,E'),(3,\varepsilon)\}>,$$
$$L_d=\{(0,Sem_{Meta}(\perp)),(1, ...),$$
$$(2,Sem_{Meta}((E.d+1)[L_d(0)/E.d])),$$
$$(3,Sem_{Meta}((E'.d)[L_d(2)/E'.d]))\}\}$$

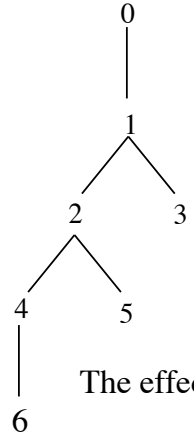
Exercise. Do the same on the grammar above, now extended by the production:
S::= E{E.d := 0}

Apply Semantics: Another Example [Aho-pag.316]

S::= U {U.count:=0}
U::= U_1 1 {U_1.count=U.count+1}
U::= ε {print(U.count}



parse tree



The effective tree

T^A={<R={0,1,2,3,4,5,6}, E, L={(0,S),(1,U),(2,U),(3,1),(4,U),(5,1),(6,ε)}>,

L_{count}={(0,Sem_{Meta}(⊥)), (1, Sem_{Meta}(0)), (2,Sem_{Meta}((U.count+1)[L_{count}(1)/U.count])),
(3,Sem_{Meta}(⊥)), (4,Sem_{Meta}((U.count+1)[L_{count}(2)/U.count])), (5,Sem_{Meta}(⊥)),
(6, Sem_{Meta}(print(U.count)[L_{count}(4)/U.count]))}

Sem_{Meta}(print(U.count)[L_{count}(4)/U.count]) = Sem_{Meta}(print(U.count+1)[L_{count}(2)/U.count])
= Sem_{Meta}(print(U.count+1+1)[L_{count}(1)/U.count])
= Sem_{Meta}(print(0+1+1))

Apply Attribute Grammar to Parse Trees: An Exercise

Let *mk-tree* be an arity-variant procedure that applies to a *label* and to n *trees* and results the tree rooted on a node having, as label, the first argument, and, as sons, the n trees, in the order of appearance from left. Say: 1) the type of the attributes; 2) the family $L_{\{ai\}}$; 3) the value of each attribute relating to 2+3.

E::= F E' [0]
E'::= + E [1]| ε [2]
F::= H F' [3]
F'::= * F [4]| ε [5]
H::= num [6]| (E) [7]

E::= F E' [0]	**E.tree:= mk-tree('E', F.tree, E'.tree), F.depth:=E.depth+1, E'.depth:=E.depth+1**
E'::= + E [1]	**E'.tree:= mk-tree('E'', mk-leaf('+'), E.tree), +.depth:=E'.depth+1,E.depth:=E'.depth+1**
E'::= ε [2]	**E'.tree:= mk-tree('E'', mk-leaf('ε')) ε,depth:=E'.depth+1**
F::= H F' [3]	**F.tree:= mk-tree('F', H.tree, F'.tree), H.depth:=F.depth+1, F'.depth:=F.depth+1**
F'::= * F [4]	**F'.tree:= mk-tree('F'', mk-leaf('*'), F.tree), *.depth:=F'.depth+1, F.depth:=F'.depth+1**
F'::= ε [5]	**F'.tree:= mk-tree('F'', mk-leaf('ε')) ε.depth:=E'.depth+1**
H::= num [6]	**H.tree:= mk-tree('H', mk-leaf(num)), num.depth:=H.depth+1**
H::= (E) [7]	**H.tree:= mk-tree('H', mk-leaf('('), E.tree, mk-leaf(')')), E.depth:= H.depth+1, (.depth:=H.depth+1,).depth:=H.depth+1,**
