### What is a type?

### Hardware

- can manage bits in different ways
- has no type, but provides operations on numbers and pointers (bit sequences)
- Software creates the abstraction of types

#### Types (1<sup>st</sup> Part)

Type checking

Types in the practice

Advanced Types

# What is a type?

### Hardware

- can manage bits in different ways
- has no type, but provides operations on numbers and pointers (bit sequences)
- Software creates the abstraction of types
- Туре
  - defines the memory layout of data
  - defines a set of operations that can be performed on value belonging to that type

### A type system consists of

- a mechanism for *defining* types and *associating* them to language structures
- a set of rules for:
  - type equivalence  $(Type_A = Type_B?)$

Types (1<sup>st</sup> Part)

#### Introduction

Type checking

ypes in the ractice

Advanced Types

- A type system consists of
  - a mechanism for *defining* types and *associating* them to language structures
  - a set of rules for:
    - type equivalence  $(Type_A = Type_B?)$
    - type compatibility (*Type*<sub>A</sub> ∈ *Context*<sub>i</sub>?)

### A type system consists of

- a mechanism for *defining* types and *associating* them to language structures
- a set of rules for:
  - type equivalence (*Type*<sub>A</sub> = *Type*<sub>B</sub>?)
  - type compatibility (*Type*<sub>A</sub> ∈ *Context*<sub>i</sub>?)
  - type inference  $(x \in Type_A?)$

#### Types (1<sup>st</sup> Part)

#### Introduction

Type checking

Types in the ractice

Advanced Types

# Type system rules (Example)

```
type equivalence (Type<sub>A</sub> = Type<sub>B</sub>?)
e.g. ls it safe to cast an integer to a char?
integer x := 26;
char a := (char)x;
```

```
■ type compatibility (Type<sub>A</sub> ∈ Context<sub>i</sub>?)
e.g. Can I add a string and a real?
string s := ''foo'';
real x := s + 5.0;
```

```
■ type inference (x ∈ Type<sub>A</sub>?)
e.g. For which types of x is f defined?
```

let f x = x + x;;

# What is type checking?

# *Type checking* is the process of ensuring that a program obeys the language's type compatibility rules

Types (1<sup>st</sup> Part)

Introduction

Type checking

Types in the practice

Advanced Types

# Strong vs. weak typing

### Strong typing

Values of one type cannot be assigned to variables of another type. Enables incredibly extensive *static compiler checks*.

### Weak typing

Values of one type can be assigned to variables of another type using implicit value conversions.

Types [1<sup>st</sup> Part]

Introduction

#### Type checking

Types in the practice

### Strong vs. weak typing (Example)

```
Strong typing check returns an error
type fruitsalad: integer;
type apple: integer;
type pear: integer;
apple a := 5;
pear p := 3
fruitsalad f := a + p;
```

Types (1<sup>st</sup> Part)

Introduction

Type checking

Types in the practice

Advanced Types

# Strong vs. weak typing (Example)

Strong typing check returns an error

```
type fruitsalad: integer;
type apple: integer;
type pear: integer;
apple a := 5;
pear p := 3
fruitsalad f := a + p;
```

```
Weak typing check goes on
type fruitsalad: integer;
type apple: integer;
type pear: integer;
apple a := 5;
pear p := 3
fruitsalad f := a + p; //fruitsalad = 8
```

Types (1<sup>st</sup> Part)

Introduction

Type checking

Types in the practice

### Dynamic vs. static typing

### Dynamic typing

Environment *infers* the type of a variable/expression from its use. It can happen both at runtime and compile-time.

### Static typing

Programmer must indicate the type of a variable/expression writing it in the code. It's checked at compile-time.

Types 1<sup>st</sup> Part

Introduction

Type checking

### Dynamic vs. static typing

### Dynamic typing

Environment *infers* the type of a variable/expression from its use. It can happen both at runtime and compile-time.

### Static typing

Programmer must indicate the type of a variable/expression writing it in the code. It's checked at compile-time.

Obviously, in real world they can be mixed!

Types 1<sup>st</sup> Part)

Introduction

Type checking

Types in the practice

# Dynamic vs. static typing (Example)

- Dynamic typing:
  - s := ''foo''; //s is string
  - n := sqrt(42); //n is real
- Static Typing:

string s := ''foo''; //s is string
real n := sqrt(42); //n is real

Types (1<sup>st</sup> Part)

Introduction

Type checking

Types in the practice

Advanced Types

# Game of types

# Types in programming languages

### boolean

- int, long, float, double (signed/unsigned)
- char (1 byte, 2 bytes)
- Enumerations
- Subrange  $(n_1..n_2)$
- Pointers
- Composite types
  - struct
  - union
  - array

#### Types 1<sup>st</sup> Part)

Advanced Types

# What is type cast?

Types (1<sup>st</sup> Part)

Introduction

Type checking

Types in the practice

Advanced Types

◆□▶ ◆□▶ ◆ □▶ ◆ □▶ - □ - のへで

- Type cast operation builds from an expression with type *TypeA* a new value of type *TypeB*
- Consider the following definitions:

```
int add(int i, int j);
int add2(int i, double j);
```

Introduction

Type checking

Types in the practice

Advanced Types

- Type cast operation builds from an expression with type *Type<sub>A</sub>* a new value of type *Type<sub>B</sub>*
- Consider the following definitions: int add(int i, int j); int add2(int i, double j);
- Ad the following calls:

```
add(2, 3); //Exact
add(2, (int)3.0); //Explicit cast
add2(2, 3); //Implicit cast
```

Introduction

Type checking

Types in the practice

Advanced Types

- In 32 bits architectures types require from 1 to 8 bytes
- Composite types (e.g. structures) are represented chaining constituent types together

Introduction

Type checking

Types in the practice

Advanced Types

・ロト ・ 日 ・ ・ 日 ・ ・ 日 ・ ・ りゃく

- In 32 bits architectures types require from 1 to 8 bytes
- Composite types (e.g. structures) are represented chaining constituent types together
- For performance reasons compilers employ padding to align fields to 4 (or 8) bytes addresses

Introduction

Type checking

Types in the practice

Advanced Types

・ロト ・ 日 ・ ・ 日 ・ ・ 日 ・ ・ りゃく

# Memory layout (Example)

Types (1<sup>st</sup> Part)

Introduction

Type checking

Types in the practice

Advancec Types

struct element {
 char name[2];
 int atomicnumber;
 float atomicweight;
 char metallic;

・ロト ・ 日 ・ ・ 日 ・ ・ 日 ・ ・ りゃく

};

# Problems with memory layout

- C requires that fields of a struct must be placed in the same order of the declaration (essential with pointers!)
- Not all languages behaves like this: for instance ML doesn't specify any order
- If the compiler can reorganize fields, "holes" are minimized: for instance packing name and metallic saves 4 bytes

・ロト ・ 日 ・ ・ 日 ・ ・ 日 ・ ・ りゃく

Types (1<sup>st</sup> Part)

Introduction

Type checking

Types in the practice

### Union

- Union types allow sharing the same memory area among different types
- The size of the value is the maximum of the size of the constituents

```
union u {
   struct element e;
   int number;
};
```

name		free	free	
atomicnumber				
atomicweight				
metallic	free	free	free	

number				
free	free	free	free	
free	free	free	free	
free	free	free	free	

Types (1<sup>st</sup> Part)

Introduction

Type checking

Types in the practice

- User defined types to increase expressivity
- Values of an enumerate are ordered and can be used as indexes of arrays or collections

enum weekday {sun, mon, tue, wed, thu, fri, sat };

#### Types (1<sup>st</sup> Part)

Introduction

Type checking

Types in the practice

Advanced Types

◆□▶ ◆□▶ ◆三▶ ◆三▶ →□ ●

- Array are *positional* collections of *homogeneous* data
- From an abstract point of view an array is a mapping from an *index type* to an *element type*
- Array's indexes

int char[26]; // C/C++

var frequency : array['a'..'z'] of integer; //Pascal

Types (1<sup>st</sup> Part)

ntroduction

Type checking

Types in the practice

Advanced Types

・ロト・西ト・山下・山下・山下・山下

- Not a real type, it's a *label*
- A pointer variable is a variable whose value is a *reference* to some object

Introduction

Type checking

Types in the practice

Advanced Types

◆□▶ ◆□▶ ◆三▶ ◆三▶ →□ ●

- Not a real type, it's a *label*
- A pointer variable is a variable whose value is a *reference* to some object
- A pointer is not an address of memory. It is an high level reference

Introduction

Type checking

Types in the practice

Advanced Types

・ロト ・ 日 ・ ・ 日 ・ ・ 日 ・ ・ りゃく

- Not a real type, it's a *label*
- A pointer variable is a variable whose value is a *reference* to some object
- A pointer is not an address of memory. It is an high level reference
- One pointer can refer to an already existing object

Type checking

Types in the practice

Advanced Types

・ロト ・ 日 ・ ・ 日 ・ ・ 日 ・ ・ りゃく

- Not a real type, it's a *label*
- A pointer variable is a variable whose value is a *reference* to some object
- A pointer is not an address of memory. It is an high level reference
- One pointer can refer to an already existing object
- A pointer can be created allocating memory for it
- A pointer that was created must be destroyed

Introduction Type checking Types in the

### Problems with pointers: memory leak

- A created pointer must be destroyed to clean memory
- A pointer variable when out of scope is lost

Types (1<sup>st</sup> Part)

Introduction

Type checking

Types in the practice

Advanced Types

### Problems with pointers: memory leak

- A created pointer must be destroyed to clean memory
- A pointer variable when out of scope is lost
- ...but the pointed object is still in memory
- The pointed object cannot be accessed but uses memory

{  
foo pf = new foo(); 
$$pf \longrightarrow foo$$
  
}  
 $pf foo$ 

Types [1<sup>st</sup> Part]

ntroduction

Type checking

Types in the practice

### Problems with pointers: dangling reference

- Suppose two pointers pointing to the same object
- When one of the two pointers is destroyed the object is removed from memory

Types (1<sup>st</sup> Part)

Introduction

Type checking

Types in the practice

Advanced Types

# Problems with pointers: dangling reference

- Suppose two pointers pointing to the same object
- When one of the two pointers is destroyed the object is removed from memory
- ...but the second pointer is a live pointer that no longer points to a valid object
- The access to the cleaned object can rise errors

foo pf1 := new foo(); foo pf2 := pf1;

delete(pf1);

Types (1<sup>st</sup> Part)

ntroduction

Type checking

Types in the practice

### Abstract data types

- According to the abstract view of types, a type is an interface
- An ADT is a set of *values* and *operations* allowed on it
- Programming languages have mechanisms to define ADT

Types 1<sup>st</sup> Part)

Introduction

Type checking

Types in the practice

Advanced Types

# Abstract data types (Example)

```
struct node {
                                                             (1<sup>st</sup> Pari
   int val;
   struct node *next;
};
struct node* next(struct node* 1) { return 1->next: }
                                                           Advanced
struct node* initNode(struct node* 1, int v) {
                                                           Types
   1->val = v; 1->next = NULL; return 1;
}
void append(struct node* 1, int v) {
  struct node p = 1;
  while (p->next) p = p->next;
  p->next =
  initNode((struct node)malloc(sizeof(struct node)),v);
}
                                 ・ロット 小田 マ イヨット エヨー うらう
```

### Abstract data types limits

- C doesn't provide any mechanism to hide the structure of data types
- A program can access next field without using the next function

Types (1<sup>st</sup> Part)

Introduction

Type checking

Types in the practice

Advanced Types

・ロト ・ 日 ・ ・ 日 ・ ・ 日 ・ ・ りゃく

### Abstract data types limits

- C doesn't provide any mechanism to hide the structure of data types
- A program can access next field without using the next function
- To hide data and to preserve abstraction we must use a *Class*

Types (1<sup>st</sup> Part)

Introduction

Type checking

Types in the practice

Advanced Types

・ロト ・ 日 ・ ・ 日 ・ ・ 日 ・ ・ りゃく

### Class type

Class is a *type constructor* like struct or array

Types 1<sup>st</sup> Part

Advanced

Types

- A class combines
  - Data (like struts)
  - Methods (operations on the data)
- A class has two special operations to provide
  - Initialization
  - Finalization

# Class type (Example)

```
class Node {
   int val;
   Node m_next;
   Node(int v) { val := v; }
   Node next() { return m_next; }
   void append(int v) {
      Node n := this;
      while (n.m_next != null) n := n.m_next;
      n.m_next := new Node(v);
   }
ł
```
